## PH3010 / MSci Skills Miniproject

## Statistical Data Analysis

## Week 1: The Method of Least Squares

Autumn term 2017
Glen D. Cowan
RHUL Physics

G. Cowan / RHUL Physics

## Outline (part 1)

Today:
Basic ideas of fitting a curve to data
The method of least squares
Finding the fitted parameters
Find the statistical errors of the fitted parameters
Using error propagation
Start of exercises

Next week:
goodness-of-fit, fitting correlated data, more exercises

## The Statistical Data Analysis Module

This module on Statistical Data Analysis contains two parts:
Curve fitting with the method of least squares (weeks 1, 2) Introduction to Machine Learning (week 3)
You will be given a number of exercises that should be written up in the form of a mini-project report. The standard rules apply:

Use the LaTeX template from the PH3010 moodle page.
Word limit is 3000 , not including appendices.
All code should be submitted as an appendix.
The exercises for the least-squares part of the module are at the end of the script on moodle. Core exercises are numbers $1,2,3$. There may be some adjustment of the assigned exercises depending on how fast we are able to get through the material. (Exercise 4 may become optional.)

## Curve fitting: the basic problem

Suppose we have a set of $N$ measured values $y_{i}, i=1, . ., N$.
Each $y_{i}$ has an "error bar" $\sigma_{i}$, and is measured at a value $x_{i}$ of a control variable $x$ known with negligible uncertainty:

Roughly speaking, the goal is to find a curve that passes "close to" the data points, called "curve fitting".

## Measured values $\rightarrow$ random variables

We will regard the measured $y_{i}$ as independent observations of random variables (r.v.s).

Idea of an r.v.: imagine making repeated observations of the same $y_{i}$, and put these in a histogram:

The distribution of $y_{i}$ has a mean $\mu_{i}$ and standard deviation $\sigma_{i}$.
We only know the data values $y_{i}$ from a single measurement, i.e., we do not know the $\mu_{i}$ (goal is to estimate this).

$$
\begin{aligned}
& y_{i}=\text { measured value } \\
& x_{i}=\text { control variable value } \\
& \mu_{i}=\text { "true value" (unknown) } \\
& \sigma_{i}=\text { error bar } \leftarrow \text { suppose these are known } \\
& \text { PH } 3010 \text { Least Squares Fitting } / \text { Week } 1
\end{aligned}
$$

## Least Squares: main idea

Consider fitting a straight line ad suppose we pick an arbitrary point in parameter space $\left(\theta_{0}, \theta_{1}\right)$, which gives a certain curve:

Here the curve does not describe the data very well, as can be seen by the large values for the residuals:

$$
\text { residual of } i^{\text {th }} \text { point }=y_{i}-f\left(x_{i} ; \boldsymbol{\theta}\right)
$$

## Least squares estimators

The values that minimize $\chi^{2}(\theta)$ are called the least-squares estimators for the parameters, written with hats:

$$
\hat{\boldsymbol{\theta}}=\left(\hat{\theta}_{0}, \hat{\theta}_{1}\right)
$$

The fitted curve is thus "best" in the least-squares sense:

$$
\begin{aligned}
& \hat{\theta}_{0}=2.258 \\
& \hat{\theta}_{1}=0.741
\end{aligned}
$$

G. Cowan / RHUL Physics

## Next steps

1. How do we find the estimators, i.e., how do we minimize $\chi^{2}(\theta)$ ?
2. How do we quantify the statistical uncertainty in the estimated parameters that stems from the random fluctuations in the measurements, and how is this information used in an analysis problem, e.g., using error propagation?
3. How do we assess whether the hypothesized functional form $f(x ; \theta)$ adequately describes the data?

## Comments on LS estimators

We can derive the method of Least Squares from a more general principle called the method of Maximum Likelihood applied to the special case where the $y_{i}$ are independent and Gaussian distributed:

$$
y_{i} \sim \operatorname{Gauss}\left(\mu_{i}, \sigma_{i}\right), \quad \mu_{i}=f\left(x_{i} ; \boldsymbol{\theta}\right)
$$

It is equally valid to take the minimum of $\chi^{2}(\theta)$ as the definition of the least-squares estimators, and in fact there is no general rule for finding estimators for parameters that are optimal in every relevant sense.

## Finding estimators in closed form

For a limited class of problem it is possible to find the estimators in closed form. An important example is when the function $f(x ; \theta)$ is linear in the parameters $\boldsymbol{\theta}$, e.g., a polynomial of order $M$ (note the function does not have to be linear in $x$ ):

$$
f(x ; \boldsymbol{\theta})=\sum_{n=0}^{M} \theta_{n} x^{n}
$$

As an example consider a straight line (two parameters):

$$
f(x ; \boldsymbol{\theta})=\theta_{0}+\theta_{1} x
$$

We need to minimize: $\quad \chi^{2}\left(\theta_{0}, \theta_{1}\right)=\sum_{i=1}^{N} \frac{\left(y_{i}-\theta_{0}-\theta_{1} x_{i}\right)^{2}}{\sigma_{i}^{2}}$

Finding estimators in closed form (2)

Set the derivatives of $\chi^{2}(\theta)$ with respect to the parameters equal to zero:

$$
\begin{aligned}
& \frac{\partial \chi^{2}}{\partial \theta_{0}}=\sum_{i=1}^{N} \frac{-2\left(y_{i}-\theta_{0}-\theta_{1} x_{i}\right)}{\sigma_{i}^{2}}=0 \\
& \frac{\partial \chi^{2}}{\partial \theta_{1}}=\sum_{i=1}^{N} \frac{-2 x_{i}\left(y_{i}-\theta_{0}-\theta_{1} x_{i}\right)}{\sigma_{i}^{2}}=0
\end{aligned}
$$

## Finding estimators in closed form (4)

Recall how to invert a $2 \times 2$ matrix:

$$
A=\left(\begin{array}{cc}
a & b \\
c & d
\end{array}\right), \quad A^{-1}=\frac{1}{a d-b c}\left(\begin{array}{cc}
d & -b \\
-c & a
\end{array}\right)
$$

Apply $A^{-1}$ to both sides of previous eq. to find solution (written with hats, because these are the estimators):

$$
\begin{aligned}
& \hat{\theta}_{0}=\frac{d e-b f}{a d-b c} \\
& \hat{\theta}_{1}=\frac{a f-e c}{a d-b c}
\end{aligned}
$$

The equations can be rewritten in matrix form as

$$
\left(\begin{array}{cc}
\sum_{i=1}^{N} \frac{1}{\sigma_{i}^{2}} & \sum_{i=1}^{N} \frac{x_{i}}{\sigma_{i}^{2}} \\
\sum_{i=1}^{N} \frac{x_{i}}{\sigma_{i}^{2}} & \sum_{i=1}^{N} \frac{x_{i}^{2}}{\sigma_{i}^{2}}
\end{array}\right)\binom{\theta_{0}}{\theta_{1}}=\binom{\sum_{i=1}^{N} \frac{y_{i}}{\sigma_{i}^{2}}}{\sum_{i=1}^{N} \frac{x_{i} y_{i}}{\sigma_{i}^{2}}}
$$

which has the general form

$$
\left(\begin{array}{cc}
a & b \\
c & d
\end{array}\right)\binom{\theta_{0}}{\theta_{1}}=\binom{e}{f} \quad \begin{aligned}
& \text { Read off } a, b, c, d \\
& e, f, \text { by comparing } \\
& \text { with eq. above. }
\end{aligned}
$$

## Comments on solution when $f(x ; \theta)$ is linear in the parameters

Finding solution requires solving a system of linear equations; can be done with standard matrix methods.
Estimators are linear functions of the $y_{i}$. This is true in general for problems of this type with an arbitrary number of parameters.

Even though we could find the solution in closed form, the formulas get a bit complicated.
If the fit function $f(x ; \theta)$ is not linear in the parameters, it is not always possible to solve for the estimators in closed form.

So for many problems we need to find the solution numerically.

## Finding LS estimators numerically

Start at a given point in the parameter space and move around according to some strategy to find the point where $\chi^{2}(\theta)$ is a minimum.

For example, alternate minimizing with respect to each component of $\boldsymbol{\theta}$ :

Many strategies possible, e.g., steepest descent, conjugate gradients, ... (see Brandt Ch. 10).

Siegmund Brandt, Data Analysis: Statistical and Computational Methods for Scientists and Engineers 4th ed., Springer 2014

## Fitting the parameters with Python (2)

The data values $\left(x_{i}, y_{i}, \sigma_{i}\right)$ need to be in the form of NumPy arrays, e.g,

```
x = np.array([1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0])
y = np.array([2.7, 3.9, 5.5, 5.8, 6.5, 6.3, 7.7, 8.5, 8.7])
sig = np.array([0.3, 0.5, 0.7, 0.6, 0.4, 0.3, 0.7, 0.8, 0.5])
```

Start values of the parameters can be specified:

$$
\mathrm{p} 0=\mathrm{np} . \operatorname{array}([1.0,1.0])
$$

To find the parameter values that minimize $\chi^{2}(\theta)$, call curve_fit:
thetaHat, cov = curve_fit(func, x, y, p0, sig, absolute_sigma=True)
Returns estimators and covariance matrix as NumPy arrays
Need absolute_sigma=True for the fit errors (cov. matrix) to have desired interpretation.

## Fitting the parameters with Python

The routine routine curve_fit from scipy.optimize can find LS estimators numerically. To use it you need:

```
import numpy as np
from scipy.optimize import curve_fit
```

We need to define the fit function $f(x ; \boldsymbol{\theta})$, e.g., a straight line:

```
def func(x, *theta):
    theta0, theta1 = theta
    return theta0 + theta1*x
```

## Statistical errors of fitted parameters

The estimators have statistical errors that are due to the random nature of the measured data (the $y_{i}$ ).
If we were to obtain a new independent set of measured values, $y_{1}, \ldots, y_{N}$, then these would in general give different values for the estimated parameters.

We can simulate the data set $y_{1}, \ldots, y_{N}$ many times with the Monte Carlo method.

For each set evaluate the estimators for $\theta_{0}$ and $\theta_{1}$ from the straight-line fit and enter into a scatter plot:

## Statistical errors of fitted parameters (2)

Project points onto the $\hat{\theta}_{0}$ and $\hat{\theta}_{1}$ axes:

Each distribution's standard deviation ( $\sim$ width) is used as a measure of the corresponding estimator's statistical error.

## Covariance etc. from straight-line fit

From the simulated values shown in the scatter plot, use standard formulae (see RHUL Physics formula book) to obtain the standard deviations and covariance:

$$
\begin{aligned}
\sigma_{\hat{\theta}_{0}} & =0.29 \\
\sigma_{\hat{\theta}_{1}} & =0.057 \\
\operatorname{cov}\left[\hat{\theta}_{0}, \hat{\theta}_{1}\right] & =-0.0142, \\
\rho & =-0.86
\end{aligned}
$$

## (Co)variance, correlation

The scatter plot of $\hat{\theta}_{0}$ versus $\hat{\theta}_{1}$ showed that if one estimate came out high, the other tended to be low and vice versa.
This indicates that the estimators are (negatively) correlated.
To quantify the degree of correlation in any two random variables $u$ and $v$ we define the covariance,

$$
\operatorname{cov}[u, v]=\langle u v\rangle-\langle u\rangle\langle v\rangle=\langle(u-\langle u\rangle)(v-\langle v\rangle)\rangle
$$

The covariance of a variable $u$ with itself is its variance $V[u]=\sigma_{u}{ }^{2}$

$$
\operatorname{cov}[u, u]=\left\langle u^{2}\right\rangle-\langle u\rangle^{2}=V[u]=\sigma_{u}^{2}
$$

The square root of the variance $=$ standard deviation $\sigma_{u}$.
$\begin{aligned} & \text { Also define dimensionless correlation } \\ & \text { coefficient (can show }-1 \leq \rho \leq 1 \text { ): }\end{aligned} \quad \rho=\frac{\operatorname{cov}[u, v]}{\sigma_{u} \sigma_{v}}$

## Covariance matrix

If we have a set of estimators

$$
\hat{\boldsymbol{\theta}}=\left(\hat{\theta}_{1}, \ldots, \hat{\theta}_{m}\right)
$$

we can find the covariance for each pair and put into a matrix

$$
U_{i j}=\operatorname{cov}\left[\hat{\theta}_{i}, \hat{\theta}_{j}\right]
$$

Covariance matrix is square and symmetric.
Diagonal elements are the variances: $\quad U_{i i}=\operatorname{cov}\left[\hat{\theta}_{i}, \hat{\theta}_{i}\right]=\sigma_{\hat{\theta}_{i}}^{2}$
The vector of estimators and their covariance matrix are the two objects returned by the routine curve_fit:
thetaHat, cov = curve_fit(func, $x, y, p 0$, sig, absolute_sigma=True)

## Covariance from derivatives of $\chi^{2}(\theta)$

It is also possible to obtain the covariance matrix from second derivatives of $\chi^{2}(\theta)$ with respect to the parameters at its minimum.

First find $U^{-1}$,

$$
U_{i j}^{-1}=\frac{1}{2}\left(\frac{\partial^{2} \chi^{2}}{\partial \theta_{i} \partial \theta_{j}}\right)_{\theta=\hat{\boldsymbol{\theta}}}
$$

and then invert to find the covariance matrix $U$.
This is what curve_fit does (derivatives computed numerically). Example with straight-line fit gives:

$$
U=\left(\begin{array}{cc}
0.08537 & -0.01438 \\
-0.01438 & 0.003275
\end{array}\right)
$$

## The error propagation formulae

By expanding the functions to first order about the parameter estimates, one can show that the covariance is approximately

$$
\operatorname{cov}[u, v] \approx \sum_{i, j=1}^{m} \frac{\partial u}{\partial \hat{\theta}_{i}} \frac{\partial v}{\partial \hat{\theta}_{j}} U_{i j}
$$

and thus the variance for a single function is

$$
\sigma_{u}^{2} \approx \sum_{i, j=1}^{m} \frac{\partial u}{\partial \hat{\theta}_{i}} \frac{\partial u}{\partial \hat{\theta}_{j}} U_{i j}
$$

In the special case where the covariance matrix is diagonal, $U_{i j}=\sigma_{i} \sigma_{j} \delta_{i j}$, we can carry out

$$
\sigma_{u}^{2} \approx \sum_{i=1}^{m}\left(\frac{\partial u}{\partial \hat{\theta}_{i}}\right)^{2} \sigma_{\hat{\theta}_{i}}^{2}
$$

## Using the covariance matrix:

error propagation
Suppose we've done a fit for parameters $\left(\theta_{1}, \ldots, \theta_{m}\right)$ and obtained estimators and their covariance matrix.

We may then be interested in a given function of the fitted parameters, e.g.,

$$
u(\hat{\boldsymbol{\theta}})=\left(\hat{\theta}_{1} \hat{\theta}_{2}-2 \hat{\theta}_{3}\right)^{2}
$$

What is the standard deviation of the quantity $u$ ? That is, how do we propagate the statistical errors in the estimated parameters through to $u$ ?
Or suppose we have two functions $u$ and $v$. What is are their standard deviations and what is their covariance $\operatorname{cov}[u, v]$ ?

## Comments on error propagation

In general the estimators from a fit are correlated, so their full covariance matrix must be used for error propagation.
The approximation of error propagation is that the functions are linear in a region of plus-or-minus one standard deviation about the estimators.

Simple example:

$$
\begin{gathered}
u=a \hat{\theta}_{1}+b \hat{\theta}_{2} \quad \frac{\partial u}{\partial \hat{\theta}_{1}}=a \quad \frac{\partial u}{\partial \hat{\theta}_{2}}=b \\
\sigma_{u}^{2}=a^{2} U_{11}+b^{2} U_{22}+a b U_{12}+b a U_{21} \\
=a^{2} \sigma_{\hat{\theta}_{1}}^{2}+b^{2} \sigma_{\hat{\theta}_{2}}^{2}+2 a b \operatorname{cov}\left[\hat{\theta}_{1}, \hat{\theta}_{2}\right]
\end{gathered}
$$

## Exercise 1: polynomial fit

Exercise 1: Polynomial fit and error analysis
Consider the following set of $(x, y, \sigma)$ data points:
$\mathrm{x}=\mathrm{np} . \operatorname{array}([1.0,2.0,3.0,4.0,5.0,6.0,7.0,8.0,9.0])$
$\mathrm{y}=\mathrm{np} . \operatorname{array}([2.7,3.9,5.5,5.8,6.5,6.3,7.7,8.5,8.7])$
$\operatorname{sig}=n p . \operatorname{array}([0.3,0.5,0.7,0.6,0.4,0.3,0.7,0.8,0.5])$
1(a): Using these data carry out the least-squares fit of an $M$ th order polynomial, i.e., with $M+1$ adjustable parameters, for $M=1,2,3$.

1(b): For each fit, use the error propagation formula Eq. (26) to find the standard deviation of the fitted function $\sigma_{f}$ as a function of $x$. Note that to do this you will need to compute the derivatives of $f(x ; \hat{\boldsymbol{\theta}})$ with respect to the components of $\hat{\boldsymbol{\theta}}$. Display the fitted curve plus-or-minus one standard deviation as a shaded band, and extend the $x$ axis to at least 20 . (The shaded band can be made with the function matplotlib.fill_between.) The result for $M=1$ is shown in Fig. 9. Note how the size of the error band increases when one goes to $x$ values outside the region where data are available; investigate how this behaviour changes as the order of the polynomial is increased.

## Polynomial fit: error propagation

Consider the difference between the fitted curve values at $x=a$ and $x=b$ :

$$
\Delta_{a b}(\hat{\boldsymbol{\theta}})=f(a ; \hat{\boldsymbol{\theta}})-f(b ; \hat{\boldsymbol{\theta}})
$$

Use error propagation to find the standard deviation of $\Delta_{a b}$ (see script).

## Polynomial fit: error band

## Ball and ramp data from Galileo

Galileo Galilei, Manuscript $f .116$, Biblioteca Nazionale Centrale di Firenze, bncf.firenze.sbn.it

In 1608 Galileo carried out experiments rolling a ball down an inclined ramp to investigate the trajectory of falling objects.

## Ball and ramp data from Galileo

| Units in punti <br> (approx. 1 mm) |  |
| :---: | :---: |
| $h$ | $d$ |
| 1000 | 1500 |
| 828 | 1340 |
| 800 | 1328 |
| 600 | 1172 |
| 300 | 800 |

Suppose $h$ is set with negligible uncertainty, and $d$ is measured with an uncertainty $\sigma=15$ punti.

## Extra slides

## Analysis of ball and ramp data

What is the correct law that relates $d$ and $h$ ?
Try different hypotheses:

$$
\begin{aligned}
& d=\alpha h \\
& d=\alpha h+\beta h^{2} \\
& d=\alpha h^{\beta}
\end{aligned}
$$

For now, fit the parameters $\alpha$ and $\beta$, find their standard deviations and covariance.

Next week we will discuss how to test whether a given hypothesized function is in good or bad agreement with the data.

## History

Least Squares fitting also called "regression"
F. Galton, Regression towards mediocrity in hereditary stature, The Journal of the Anthropological Institute of Great Britain and Ireland. 15: 246-263 (1886).

Developed earlier by Laplace and Gauss:
C.F. Gauss, Theoria Motus Corporum Coelestium in Sectionibus Conicis Solem Ambentium, Hamburgi Sumtibus Frid. Perthes et H. Besser Liber II, Sectio II (1809);
C.F. Gauss, Theoria Combinationis Observationum Erroribus Minimis Obnoxiae, pars prior (15.2.1821) et pars posterior (2.2.1823), Commentationes Societatis Regiae Scientiarium Gottingensis Recectiores Vol. V (MDCCCXXIII).
