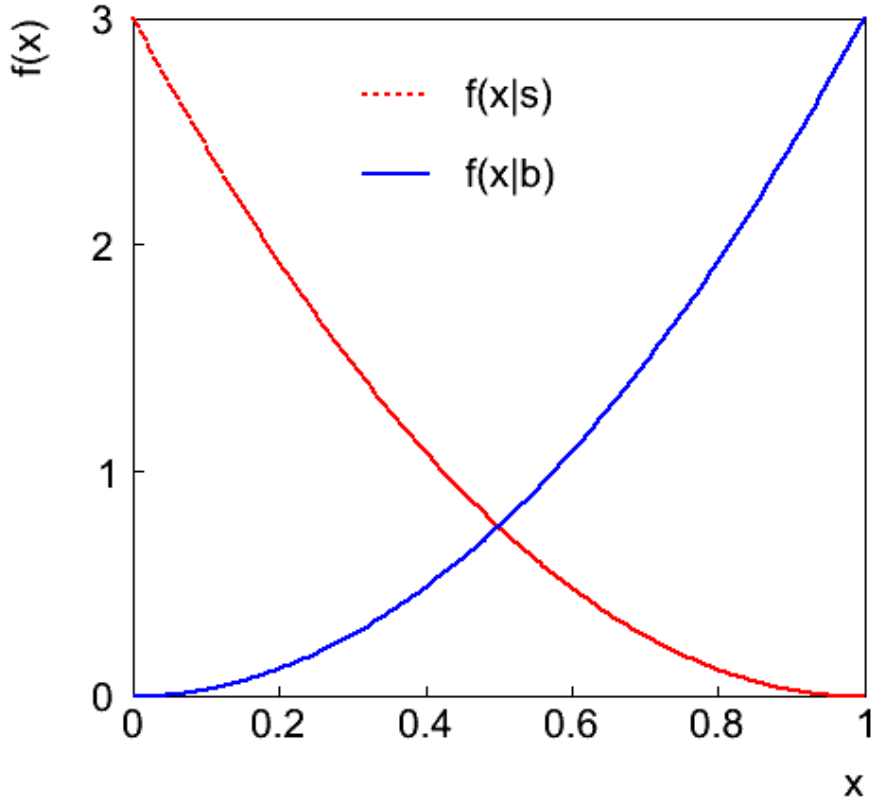
Problem 1 – discovering a small signal

Materials at **www.pp.rhul.ac.uk/~cowan/stat/invisibles/**

Problem concerns searching for a signal such as Dark Matter by counting events. Suppose signal/background events are characterized by a variable x ($0 \le x \le 1$):

$$f(x|s) = 3(1-x)^2 ,$$

$$f(x|b) = 3x^2 .$$



As a first step, test the background hypothesis for each event: if $x < x_{\text{cut}}$, reject background hypothesis.

Testing the outcome of the full experiment

In the full experiment we will find n events in the signal region ($x < x_{\text{cut}}$), and we can model this with a Poisson distribution:

$$P(n|s,b) = \frac{(s+b)^n}{n!} e^{-(s+b)}$$

Suppose total expected events in $0 \leq x \leq 1$ are $b_{\text{tot}} = 100$, $s_{\text{tot}} = 10$; expected in $x < x_{\text{cut}}$ are s, b.

Suppose for a given x_{cut}, $b = 0.5$ and we observe $n_{\text{obs}} = 3$ events. Find the p-value of the hypothesis that $s = 0$:

$$p = P(n \geq n_{\text{obs}}|s=0,b) = \sum_{n=n_{\text{obs}}}^{\infty} \frac{b^n}{n!} e^{-b} = 1 - \sum_{n=0}^{n_{\text{obs}}-1} \frac{b^n}{n!} e^{-b}$$

and the corresponding significance: $Z = \Phi^{-1}(1-p)$

Experimental sensitivity

To characterize the experimental sensitivity we can give the median, assuming s and b both present, of the significance of a test of $s = 0$. For $s \ll b$ this can be approximated by

$$\mathrm{med}[Z_b|s+b] = s/\sqrt{b}$$

A better approximation is:

$$\mathrm{med}[Z_b|s+b] = \sqrt{2\left((s+b)\ln\left(1+\frac{s}{b}\right)-s\right)}$$

Try this for $x_{\mathrm{cut}} = 0.1$ and if you have time, write a small program to maximize the median Z with respect to x_{cut}.

Tomorrow we will discuss methods for including uncertainty in b.

Using the x values

Instead of just counting events with $x < x_{\text{cut}}$, we can define a statistic that takes into account all the values of x. I.e. the data are: $n, x_1, .., x_n$. Tomorrow we will discuss ways of doing this with the likelihood ratio L_{s+b}/L_b, which leads to the statistic

$$q = -2\sum_{i=1}^{n}\left[1 + \frac{s_{\text{tot}}}{b_{\text{tot}}}\frac{f(x_i|s)}{f(x_i|b)}\right]$$

Using **`www.pp.rhul.ac.uk/~cowan/stat/invisibles/mc/invisibleMC.cc`** find the distribution of this statistic under the "b" and "$s+b$" hypotheses.

From these find the median, assuming the $s+b$ hypothesis, of the significance of the b (i.e., $s = 0$) hypothesis. Compare with result from the experiment based only on counting n events.

Further problems

See **www.pp.rhul.ac.uk/~cowan/stat/freiburg/SigCalc/** for a related problem based on the profile likelihood ratio. The mathematics is similar to the procedure used by XENON100 in Phys. Rev. D 84, 052003 (2011); arXiv:1103.0303.

You can get all the files from **www.pp.rhul.ac.uk/~cowan/stat/freiburg/SigCalc.tar** (copy to working directory and unpack with **tar -xvf SigCalc.tar**)

Some exercises on multivariate methods (neural networks, boosted decision trees, etc.) can be found here:
